## **Site Preference for Spinels and Inverse Spinels**

Question: Why does some AB<sub>2</sub>O<sub>4</sub> compounds having transition elements as A and /or B prefer the inverse Spinel structure and some others normal Spinel structure?

$$Mn_3O_4 = Mn^{||}Mn^{||}_2O_4$$

 $O^{2-}$  = a weak field ligand

 $Mn^{2+} = d^5 HS : CFSE = 0$ 

 $Mn^{3+} = d^4 HS : CFSE = -0.6 \Delta_o$ 

Mn<sup>2+</sup> by exchanging positions with Mn<sup>3+</sup> in an octahedral hole is not going to gain any extra crystal field stabilization energy. While Mn<sup>3+</sup> by being in the octahedral hole will have CFSE. Therefore Mn<sub>3</sub>O<sub>4</sub> will be Normal Spinel

$$Fe_3O_4 = Fe^{\parallel}Fe^{\parallel}_2O_4$$

Fe<sup>2+</sup> = d<sup>6</sup> HS : CFSE =-0.4  $\Delta_o$ 

 $Fe^{3+} = d^5 HS: CFSE = 0$ 

Fe<sup>2+</sup> by exchanging positions with Fe<sup>3+</sup> to an octahedral hole is going to gain extra crystal field stabilization energy. While Fe<sup>3+</sup> by being in the octahedral hole will not have any CFSE. Therefore Fe<sub>3</sub>O<sub>4</sub> will be Inverse Spinel

• Based on CFSE values, it is possible to predict the type of compounds having the formula  $AB_2O_4$  whether it belongs to normal spinels or Inverse Spinels

## **Merits of crystal Field Theory**

- ➤ Predict most favorable geometry of a complex
- > Accounts for four coordinated complexes (tetrahedral and square planar)
- Explains the ligands forming outer / inner orbital complexes (high spin / low spin)
- ➤ Interprets magnetic properties taking in to consideration the orbital contributions also
- ➤ Interprets color of transition metal complexes
- > Explains spectral properties of many transition metal complexes
- > Predict site selection in spinel and antispinel structures

## **Limitations of CFT**

- $\triangleright$  CFT considers only the metal ion d-orbitals and gives no consideration at all to other metal orbitals such as s-, p-orbitals and the ligand  $\pi$ -orbitals. Therefore, to explain all the properties of the complexes dependent on the  $\pi$ -ligand orbitals will be outside the scope of CFT. This does not consider the formation of  $\pi$ -bonding in complexes.
- Less accurate when **covalent bonding increases or partly covalent nature of the metal-ligand bonds** (As ligand orbital and electrons become more important). Bonding strength and chemical properties cannot be explained in some complexes based on only electrostatic interactions (purely ionic) as assumed by the theory
- ➤ CFT is unable to account satisfactorily for the **relative strengths of ligands**, e.g. it gives no explanation as to why H<sub>2</sub>O appears in the spectrochemical series as a stronger ligand than OH<sup>-</sup>

## **Preparation of Complex Compounds**

- > Complexes are prepared by the following types of reactions:
- > Connection Reactions:

$$Hgl_2 + 2KI \rightarrow K_2[Hgl_4]$$

> Substitution Reactions:

$$[Cu(H_2O)_4]SO_4 + 4NH_3 \rightarrow [Cu(NH_3)_4]SO_4 + 4H_2O$$

> Exchange Reactions:

$$2ZnCl_2 + K_4[Fe(CN)_6] \rightarrow Zn_2[Fe(CN)_6] + 4KCl$$

Redox Reactions:

$$2AI + 6KOH + 6H_2O \rightarrow K_3[AI(OH)_6] + 3H_2$$
